

18th March 2024

# YARMANY EXPLORATION UPDATE AND NEW TENEMENT ACQUISITION

## **HIGHLIGHTS:**

- First phase of regional aircore drilling campaign completed with 136 holes drilled for 5,724m
- Majority of phase 1 drilling targeted the untested southern greenstone sequence and associated pegmatites for lithium and early-stage indicators of nickel sulphide and gold mineralisation
- Several thick buried pegmatite units have been drilled in close proximity to the Ida Fault, which is considered a major controlling regional structure important for pegmatite-hosted LCT mineralisation
- Following receipt of assay results in 3-4 weeks, phase 2 of the aircore program will commence in Q2 2024
- Tenements E15/2036 and E15/2041 acquired to the south of the Yarmany Project, proximal to the Ida Fault and covering over 35km<sup>2</sup> with untested mapped pegmatite occurrences

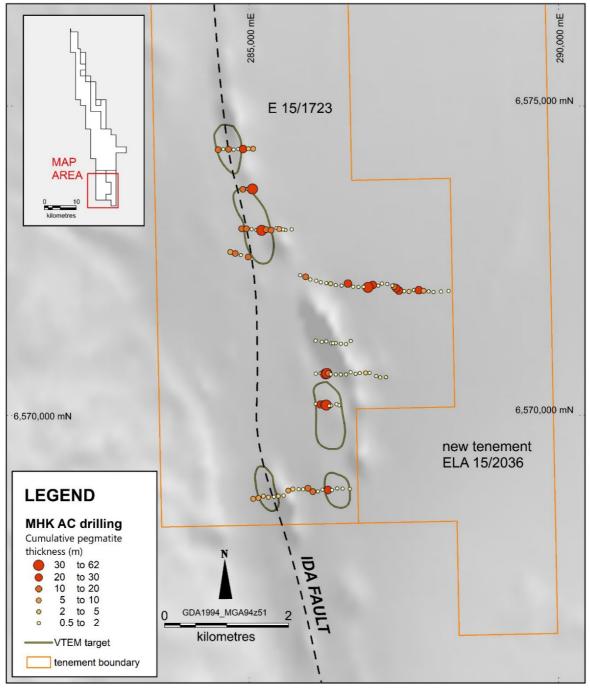

Metal Hawk Limited (**ASX: MHK**, "**Metal Hawk**", "the **Company**") is pleased to provide an update on exploration activities at the Yarmany Project, located 40km north-west of Coolgardie in Western Australia. Yarmany covers an area of more than 300km² with 50km of strike along the Ida Fault, a major regional structure on the western margin of the Kalgoorlie Terrane.

The first phase of a regional aircore (AC) program has been completed, with 136 holes drilled for a total of 5,724m. The program tested a number of geochemical, geological and geophysical target areas prospective for lithium, nickel sulphide and gold mineralisation along the Ida Fault. Most of the drilling was conducted at the southern Yarmany project area (Figure 1), which is lacking any significant outcrop and is covered by a thin layer of sand and ferricrete (typically between 2 - 6 metres). Four of the traverses also drill-tested above VTEM (versatile time-domain electromagnetic) conductors located along the margins of the extensive ultramafic target units.

**Metal Hawk's Managing Director Will Belbin commented**: "With effective and systematic low-cost exploration, we are continuing to advance our geological understanding at Yarmany. We are pleased to report the presence of thick, buried pegmatites identified in a large proportion of the aircore holes drilled, and we look forward to the results in 3-4 weeks prior to the commencement of the next phase of drilling."

"The new tenements acquired at the southern end of Yarmany increases our strong ground position along the highly prospective Ida Fault. This is an area where we are focusing a lot of our current and near-term exploration activities."

**Figure 1.** AC drilling at Yarmany south showing cumulative pegmatite thicknesses intersected and VTEM target outlines

Geological observations from this program are encouraging for further regional lithium exploration, with variably weathered thick pegmatites intersected in a large proportion of the holes. Significant thick intervals of ultramafic lithologies were also logged in several holes drilled.

An additional 13 follow-up AC holes were drilled immediately south of the F-camp prospect where previous work has identified fractionated and fertile pegmatites. Observations from the drilling were in line with expectations of a concealed pegmatite, and the Company has plans for deeper RC drilling at the prospect in the near future.

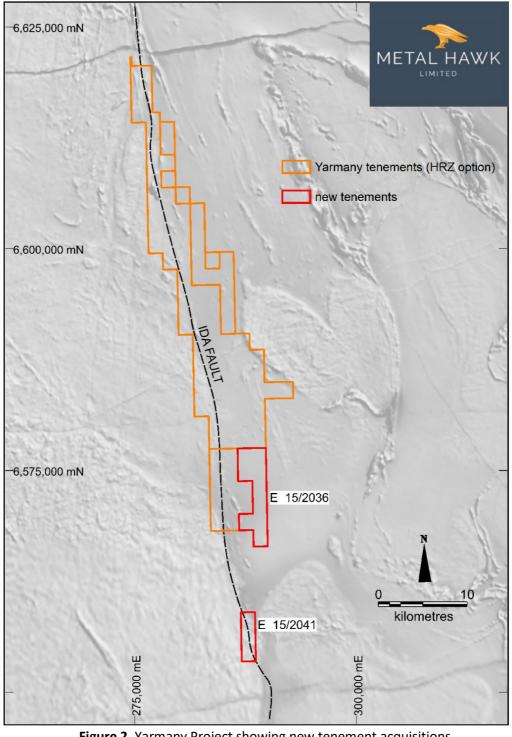

Figure 2. Yarmany Project showing new tenement acquisitions

Results from the program are expected in 3-4 weeks, and will help refine the next phase of drilling scheduled to commence in Q2 2024. In the meantime the Company's geologists are continuing mapping and geochemical sampling activities over the very large unexplored tenement area.

## **NEW KEY TENEMENTS ACQUIRED**

Metal Hawk has purchased two tenement applications E 15/2036 and E 15/2041 from LCT Precious Metals Pty Ltd for \$7,500 cash, \$70k worth of MHK shares, plus a 1% NSR. The arrangement secures a potentially important parcel of untested tenure adjoining the southeastern boundary of the Yarmany Project.

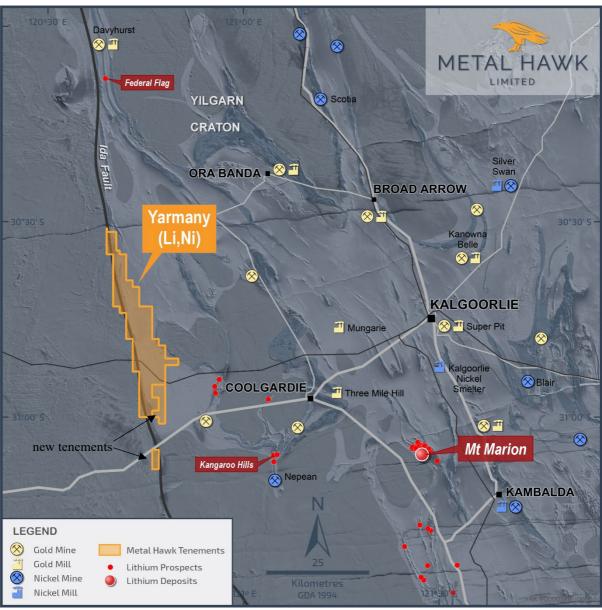

Figure 3. Yarmany Project location

This announcement has been authorised for release by Mr Will Belbin, Managing Director, on behalf of the Board of Metal Hawk Limited.

### **Competent Person statement**

The information in this announcement that relates to Exploration Targets and Exploration Results is based on information compiled and reviewed by Mr William Belbin, a "Competent Person" who is a Member of the Australian Institute Geoscientists (AIG) and is Managing Director at Metal Hawk Limited. Mr Belbin is a full-time employee of the Company and hold shares and options in the Company. Mr Belbin has sufficient experience relevant to the style of mineralisation and type of deposit under consideration and to the activity which he has undertaken to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for the Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Mr Belbin consents to the inclusion in the report of the matters based on his information in the form and context in which it appears.

#### **Forward-Looking Statements**

This document may include forward-looking statements. Forward-looking statements include, but are not limited to, statements concerning Metal Hawk Limited's planned exploration program(s) and other statements that are not historical facts. When used in this document, the words such as "could," "plan," "estimate," "expect," "intend," "may", "potential," "should," and similar expressions are forward looking statements.

## 2012 JORC Table 1

## **SECTION 1: SAMPLING TECHNIQUES AND DATA**

	JORC Code explanation	Commentary
Sampling techniques	Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation,	136 aircore (AC) holes for a total of 5,724m were completed as part of this program. Hole depths ranged from 8m to 95m.
	such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the	The majority of AC holes were drilled vertical (-90°) and some drilled angled to towards 145° and 245°.
	broad meaning of sampling.	Drill collar summary in Table 1 in the body of this announcement.
	Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used	Logging of drill samples included lithology, colour, weathering, texture, moisture and contamination. Sampling protocols and QAQC are as per industry best practice procedures.
	Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse	Sampling was undertaken using standard industry practices.
	circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g. submarine nodules)	AC drilling was sampled using a combination of composite sampling (2-10m) and single 1m sampling, averaging 4m in length. The entire drilled intervals of all holes were sampled. In all, 1189 AC samples were collected, including QAQC.
	may warrant disclosure of detailed information.	Sample weights are typically 1-3kg for 1m samples and 2-5kg for composites.  All samples were sent to Intertek Genalysis in
		Kalgoorlie for analysis (see below).
Drilling techniques	Drill type (e.g. core, reverse circulation, open- hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g. core diameter, triple or standard tube, depth of diamond tails, face- sampling bit or other type, whether core is oriented and if so, by what method, etc).	AC drilling was undertaken by KTE Drilling based in Kalgoorlie using a 4x4 mounted aircore drill rig and 85mm blade or slimline hammer bit.
Drill sample recovery	Method of recording and assessing core and chip sample recoveries and results assessed	AC sample condition was visually assessed and noted during sampling and was found to dry in all but a few cases, where damp spoils were noted.
	Measures taken to maximise sample recovery and ensure representative nature of the samples	The recovery was considered normal for this type of drilling and with groundwater present in some holes.
	Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.	All AC holes were generally drilled to blade refusal, however, on ~10% of occasions, a hammer bit was then used to extend the hole into harder lithologies. Holes were then terminated when penetration rates became impractical otarget depth was reached.

#### Logging

Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies.

Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography.

The total length and percentage of the relevant intersections logged.

A qualified geologist logged all drill holes in full and supervised the sampling.

AC holes were logged in full.

Photographs were taken of all sample spoils and chip trays.

#### Sub-sampling techniques and sample preparation

If core, whether cut or sawn and whether quarter, half or all core taken.

If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.

For all sample types, the nature, quality and appropriateness of the sample preparation technique.

Quality control procedures adopted for all subsampling stages to maximise representivity of samples.

Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.

Whether sample sizes are appropriate to the grain size of the material being sampled.

1-metre interval drill spoils are passed through a cyclone and collected in a bucket which was then emptied on the ground for logging and sampling purposes. A 400g-1000g sub-sample was taken from each one-metre interval using a sampling scoop. Sub-samples for single (1m) or composite intervals were then placed in a pre-numbered calico bag.

Sample preparation at Intertek Genalysis Laboratories, Kalgoorlie, included sorting, drying and pulverizing (85% passing 75  $\mu$ m) in a LM5 steel mill.

Field QC procedure involves certified reference material ("CRM"), inserted by MHK in the field, at a rate of approximately 1:50 each. Laboratory QAQC results (repeats, standards, blanks) are reported by the laboratory with final assay results.

Review of the various QAQC data indicate that sampling and analysis methodology are reasonable for this stage of exploration.

The sample size is considered adequate to minimise particle size effects at this early stage of exploration. However, more rigorous sample procedures, including use of a rotary splitter and spearing composite samples, will be implemented once economic grades are encountered.

### Quality of assay data and laboratory tests

The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.

For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.

Nature of quality control procedures adopted (e.g. standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.

All MHK samples are being analysed at Intertek Genalysis in Perth for 48 elements via four acid digest with ICP-OES and ICP-MS finish (lab code "4A/MS"). This digest is considered near total, but some refractory phases may remain undissolved or partly dissolved, including cassiterite, tantalite and zircon. The detection limit for lithium is 0.1ppm.

Should economic mineralisation be encountered, MHK will implement a trigger for sodium peroxide fusion and ICP-OES for lithium and associated target elements such as Sn, Ta and Nb. This method is considered to be a total digest.

No geophysical tools have been utilised for reporting herein. Handheld XRF is used ad hoc in the field to identify rocktypes and alteration.

Internal laboratory control procedures involve repeat assaying of randomly selected assay pulps as well as internal laboratory standards. All of

		these data are reported to the Company and analysed for consistency and any discrepancies.
Verification of sampling and assaying	The verification of significant intersections by either independent or alternative company personnel.	Senior personnel from the Company have visually inspected drill samples.
	The use of twinned holes.	No assays are reported in this announcement.
	Documentation of primary data, data entry	No holes were twinned in the current program.
	procedures, data verification, data storage (physical and electronic) protocols.  Discuss any adjustment to assay data.	Primary AC data were collected using a standard set of Excel templates on a Toughbook laptop computer in the field or on hand-written log-sheets and then entered into the template. Data are entered using validation look-up-tables. These data are checked, validated and transferred to the company database.
Location of data points	Accuracy and quality of surveys used to locate drillholes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.  Specification of the grid system used.  Quality and adequacy of topographic control.	Drillhole locations were established by handheld GPS. Collar coordinates are in UTM grid (GDA2020 z51). The GPS has an east/north accuracy of +/-4m, and for waypoint averaging +/-2m. The RL from the GPS is considered inaccurate (+/-20m) and 3D drill data analysis is carried out using a nominal RL of 500m. This is considered reasonable, as topography is very flat, with small differences in elevation between drill locations. More precise RLs will be required for economic intersections in the future. These might
		be determined by DGPS or DTM.  Drill collar summary in Table 1 in body of report.
Data spacing and distribution	Data spacing for reporting of Exploration Results.  Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.	The AC drillhole spacing along lines are between 10m and 200m apart, with most being 80m. Hole spacing was determined on the fly by the geologists based on results and objectives. The line spacings are a minimum of 400m north-south.  Data from AC drilling is not suitable for estimation of Mineral Resources.
	Whether sample compositing has been applied.	Field sample compositing occurred over 2m to 10m intervals. No subsequent compositing has taken place.
Orientation of data in relation to geological structure	Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.  If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.	Drill holes were mostly positioned so that drilling was essentially perpendicular to the orientation of targeted pegmatite sheets. The pegmatite sheets are interpreted to be flat-lying to shallow west dipping, hence subsequent vertical drillhole dips All drill traverses were along east-west lines cleared by back-hoe.  No sampling bias is believed to have been introduced.
Sample security	The measures taken to ensure sample security.	Sample security for drilling is managed by the Company. After preparation in the field, samples are packed into labelled polyweave bags and dispatched by MHK to the laboratory preparation facility in Kalgoorlie. The assay laboratory audits the samples on arrival and reports and discrepancies back to the Company.

Audits	or
review	ıs

The results of any audits or reviews of sampling techniques and data.

No review of the sampling techniques has been carried out.

## **SECTION 2: REPORTING OF EXPLORATION RESULTS**

Criteria	JORC Code explanation	Commentary
Mineral tenement and land tenure status	Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings.	The Yarmany drill programs were conducted on the exploration licenses 15/1723, E15/1655, 16/503 and 15/507. The tenements are registered to Black Mountain Gold Limited. Metal Hawk has acquired an option to explore on the tenements.
	The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.	The tenements are in good standing and no known impediments exist.
Exploration done by other parties	Acknowledgment and appraisal of exploration by other parties.	Previous exploration has been carried out in the area by Matsa Resources, Metaliko Resources, Delta Gold and Horizon Minerals. Prior to Horizon's work, no previous lithium exploration has been carried out on the tenements. Their exploration was largely focused on nickel and gold, and the lithium component could be considered cursory.
Geology	Deposit type, geological setting and style of mineralisation.	The Yarmany Project is centred along the boundary of the Mt Ida Greenstones (Eastern Goldfields Superterrane) and Youanmi Terrane, represented by the Ida Fault, a significant Craton-scale structure.
		The geological setting is of Archaean age with common host rocks related to komatiite-hosted nickel sulphide mineralisation as found throughout the Yilgarn Craton of Western Australia. The region is also made up of mafic and felsic volcanics, siliciclastic metasediments of upper greenschist facies and post-orogenic S-type muscovite-bearing granites.
		Additional potential has been recently recognized for lithium mineralisation related to pegmatite occurrences that are interpreted to be late-stage volatile-rich emanations from the granites.
		Evidence for lithium potential at Yarmany is the Kathleen Valley (Liontown Resources) and Mt Ida (Delta Lithium) deposits to the north on the eastern margin of the Ida Fault.
Drill hole Information	A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes:  • easting and northing of the drill hole collar • elevation or RL (Reduced Level – elevation above sea level in	Refer to tables and the text of this announcement.  No assay results are being reported in this announcement.
	metres) of the drill hole collar     dip and azimuth of the hole     down hole length and interception depth     hole length.	

		ASX ANNOUNCEMENT
Data aggregation methods	In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (e.g. cutting of high grades) and cut-off grades are usually Material and should be stated.  Where aggregate intercepts incorporate short lengths of high grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail.  The assumptions used for any reporting of metal equivalent values should be clearly stated.	No assay results are reported in this announcement.
Relationship between mineralisation widths and intercept lengths	These relationships are particularly important in the reporting of Exploration Results.  If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported.  If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (e.g. 'down hole length, true width not known').	No assay results are reported in this announcement.
Diagrams	Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views.	Refer to Figures in text.
Balanced reporting	Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results.	No assay results are reported in this announcement.
Other substantive exploration data	Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples — size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.	All meaningful and material information has been included in the body of this announcement.
Further work	The nature and scale of planned further work (e.g. tests for lateral extensions or depth extensions or large-scale step-out drilling).  Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive	AC and targeted RC drilling are at various stages of planning to progress exploration at Yarmany.  Numerous untested targets have been generated and planning of target follow up for lithium exploration is well advanced. Only 15% of the tenement area has been assessed thus far, where it is amenable to simple surface programs. A large proportion of the project is covered by a few metres of cover and is amenable to shallow low-cost drilling techniques.
